SENTINEL

MFA Exam Hall Security System

Complete Presentation Script — 25 Minutes

RACHANA = Blue	PERSON 2 = Green	PERSON 3 = Purple	⟶ CUE = Action needed

SECTION 1 — Opening & Problem Statement | 0:00 – 2:00

NOTE: Person 2 stands and speaks. Rachana holds the hardware. Person 3 has dashboard visible on screen.

PERSON 2: Good morning. We are presenting SENTINEL — a Multi-Factor Authentication based Exam Hall Security System.

PERSON 2: Let me start with the problem. In most colleges today, exam attendance works like this: the invigilator calls names one by one. Students sign a sheet. It takes 10 to 15 minutes. Signatures can be forged. Students enter the wrong hall. And when the exam ends, nobody knows exactly who was present, at what time, and with what proof.

PERSON 2: SENTINEL eliminates all of this. Students enter in 3 to 5 seconds. Entry is verified with two factors — RFID card and face recognition. Photo proof is stored. Wrong rooms are caught immediately. And the admin sees everything live on a dashboard.

⟶ CUE: Person 3: show the dashboard home screen on laptop
⟶ CUE: Rachana: hold up the WROOM board so evaluators can see the OLED home screen

PERSON 2: What you see here is the SENTINEL home screen — on the OLED display at the door, and the admin dashboard on the laptop.

SECTION 2 — System Architecture | 2:00 – 5:00

NOTE: Person 3 speaks. Rachana holds WROOM in one hand and CAM in the other. Person 2 points to server.py terminal.

PERSON 3: SENTINEL has three hardware nodes, all communicating wirelessly over WiFi. Let me explain each one.

PERSON 3: First — the ESP32 WROOM. This is the door controller. It reads the RFID card, takes keypad input, shows messages on the OLED screen, controls the buzzer and LED, and monitors the ultrasonic sensor for trespass detection.

→ CUE: Rachana: hold up the WROOM board clearly

PERSON 3: Second — the ESP32-CAM. This is the camera node. Its only job is to capture photos and send them for processing. It handles face verification, QR scanning, and trespass snapshots.

→ CUE: Rachana: hold up the ESP32-CAM board

PERSON 3: Third — the laptop running server.py. This is the brain. It handles face recognition using DeepFace with the ArcFace model, QR verification, database operations, SMS notifications, and the admin dashboard.

→ CUE: Person 2: point to running server.py terminal

PERSON 3: The three nodes communicate over WiFi using two protocols. HTTP for direct server requests — when the WROOM needs to verify an RFID card, it sends an HTTP POST to server.py and waits for the response. And MQTT for camera commands — when the WROOM needs a face scan, it publishes a command to the MQTT broker, the CAM receives it, captures the photo, and publishes the result back.

PERSON 3: We use MQTT for the camera because it is asynchronous and lightweight — perfect for microcontrollers. The WROOM doesn't need to know the CAM's IP address, and the CAM doesn't need to know the WROOM's. They both just talk through the broker.

PERSON 2: The MQTT broker is Mosquitto, running locally on the laptop. No internet required during exams.

SECTION 3 — Live Demo | 5:00 – 16:00

NOTE: This is the most important section. All three stay active throughout. Read the CUEs carefully.

Demo Step 1 — Faculty Authentication (5:00 – 6:30)

NOTE: Person 2 narrates. Rachana operates keypad. Person 3 watches server.py terminal.

PERSON 2: Let's start with faculty authentication. Before students can enter, the invigilator must activate the session by entering their PIN. This generates the student emergency PIN and sends an SMS.

→ CUE: Rachana: press C on the keypad

RACHANA: The faculty presses C. The OLED now shows Faculty Login — Enter PIN.

→ CUE: Rachana: type 1 2 4 5 then press C

RACHANA: Entering the PIN — only digits 1, 2, 4, 5, 7, and 8 are allowed. Digits 3, 6, and 9 are reserved for keypad functions like clear and exit mode. We made this design decision to prevent a PIN digit from accidentally triggering a system command mid-entry.

PERSON 2: On the server side, the PIN is validated against the exam_sessions table in the database for today's date and this specific room. On success, a 6-digit student emergency PIN is generated using SHA256 hashing of the session ID and today's date — so it's unique every day.

→ CUE: Person 3: point to server.py log showing FACULTY OK and Student PIN

PERSON 3: You can see the server log showing authentication success and the generated student PIN. This PIN is also sent via SMS to the invigilator's registered phone number through Fast2SMS.

Demo Step 2 — Primary Student Entry: RFID + Face (6:30 – 9:30)

NOTE: Person 3 taps card. Rachana holds CAM steady at face height. Person 2 narrates server activity.

PERSON 3: Now the primary student entry flow. The student presses A and taps their RFID card.

→ CUE: Person 3: press A, then tap RFID card on the reader

RACHANA: The RC522 RFID reader reads the card's 4-byte unique ID. The WROOM immediately sends this to server.py via HTTP to check which student this is and whether they're assigned to this room.

PERSON 2: Server.py looks up the student in the database by their RFID UID. If they're in the wrong room, the system rejects them immediately at this stage — before the face scan even starts. This is important because it saves time and prevents the CAM from scanning the wrong person.

→ CUE: Person 2: point to OLED showing Welcome + student name

PERSON 3: The OLED shows the student's name and seat number. The WROOM then pings the ESP32-CAM to confirm it's online, then sends a face verification command via MQTT.

→ CUE: Rachana: hold the CAM at face height, pointing at Person 3's face

RACHANA: The ESP32-CAM captures a QVGA frame — 320 by 240 pixels — and sends it to server.py as a multipart HTTP POST. No flash for face scanning, because harsh flash at close range washes out facial features.

PERSON 2: Server.py receives the image and runs DeepFace with the ArcFace model. ArcFace extracts a 512-dimensional mathematical embedding of the face — essentially a unique fingerprint — and compares it against stored reference photos using cosine distance. A distance below 0.40 means it's the same person.

→ CUE: Person 2: point to server log showing Face prediction and distance value
→ CUE: Person 3: point to OLED showing ENTRY GRANTED

PERSON 3: Entry granted. The green LED turns on, three beeps confirm success, and the entry is logged to the database with timestamp, method used, and confidence score.

Demo Step 3 — Wrong Room Detection (9:30 – 10:30)

NOTE: Rachana taps Umehani's card (assigned to HALL-B). Person 2 narrates.

PERSON 2: SENTINEL detects wrong rooms instantly. Watch what happens when a HALL-B student tries to enter HALL-A.

→ CUE: Rachana: press A, tap Umehani's RFID card

RACHANA: This card belongs to a student assigned to HALL-B. The moment the RFID is checked, the server sees the room mismatch and returns wrong room — before any face scanning happens.

→ CUE: Person 2: point to OLED showing WRONG ROOM

PERSON 2: The OLED shows the correct hall the student should go to. Two long buzzer beeps. No face scan wasted. In a real exam hall this prevents the confusion of students discovering they're in the wrong room after sitting down.

Demo Step 4 — Trespass Detection (10:30 – 12:00)

NOTE: Rachana walks toward HC-SR04 without pressing A. Person 3 watches dashboard. Person 2 narrates.

PERSON 2: The HC-SR04 ultrasonic sensor continuously monitors the doorway. If someone approaches without authenticating, it triggers the alarm.
→ CUE: Rachana: stand at home screen (don't press A), walk slowly toward the sensor
RACHANA: The sensor requires three consecutive close readings — that's about 1.8 seconds of someone being within range — before triggering. This prevents false alarms from brief movements or sensor noise.
→ CUE: Wait for buzzer alarm to fire
PERSON 3: Ten rapid beeps and LED flashes. The ESP32-CAM automatically captures a snapshot as photo evidence. The anomaly is logged with timestamp and room ID.
→ CUE: Person 3: show anomaly appearing on dashboard
PERSON 2: The admin dashboard shows the trespass alert in real time. In a real deployment, this would alert the examination officer immediately.

Demo Step 5 — QR Fallback (12:00 – 14:00)

NOTE: Person 2 holds QR to laptop webcam. Rachana presses keys. Person 3 narrates.

PERSON 3: If face recognition fails — maybe the student has a bandage or different lighting — they can use the QR fallback. Every student has a QR code on their hall ticket.
→ CUE: Rachana: press A, tap card, then press B, then press 7
PERSON 3: The fallback menu appears. Pressing 7 triggers QR scan mode. Instead of using the ESP32-CAM — which has a fixed focus lens — we use the laptop webcam for QR scanning. This is actually how many real exam systems work — a dedicated scanner at the verification terminal.
→ CUE: Person 2: hold printed QR or phone screen with QR to laptop webcam
PERSON 2: The webcam window opens with a green guide box. The student holds their hall ticket QR inside the box. The system tries seven different decoding strategies — raw, grayscale, contrast enhancement, threshold, sharpening, upscaling — until it decodes successfully.

PERSON 3: The QR contains the student's UUCMS ID, room ID, and exam series dates, all signed with a SHA256 cryptographic hash using a secret key. If anyone tampers with the QR — changes the room or roll number — the hash won't match and it's rejected. The same QR can be used once per exam day, then resets at midnight for the next exam.
→ CUE: Point to OLED showing QR ACCEPTED ENTRY GRANTED

Demo Step 6 — Dashboard Overview (14:00 – 16:00)

NOTE: Person 3 navigates dashboard. Person 2 narrates. Rachana stands by hardware.

PERSON 3: Let me show the admin dashboard quickly.
→ CUE: Person 3: click through Logs tab
PERSON 2: The Logs tab shows every entry attempt in real time — student name, roll number, method used, confidence score, entry time, exit time. It updates every 3 seconds automatically.
→ CUE: Person 3: click Absentees tab

PERSON 3: The Absentees tab shows students who haven't entered yet today. The admin can export this as CSV instantly.

→ CUE: Person 3: click Students tab, click Hall Ticket for one student

PERSON 2: From the Students tab, the admin can generate a hall ticket PDF for any student with a single click. The PDF includes the student's details, exam information, QR code, and instructions — ready to print and distribute.

SECTION 4 — Technical Deep Dive | 16:00 – 20:00

NOTE: Each person takes one topic. 90 seconds each. Confident and clear.

Person 2 — Face Recognition (16:00 – 17:30)

PERSON 2: For face recognition we use DeepFace with the ArcFace model. ArcFace is trained on 5.8 million face images and achieves 99.4% accuracy on the standard LFW benchmark — the same benchmark used by Facebook and Google to evaluate their systems.

PERSON 2: The way it works: ArcFace extracts a 512-dimensional embedding from a face image — think of it as a mathematical fingerprint with 512 numbers. When a student stands at the door, we extract their embedding and compare it against their stored reference photo using cosine distance. A distance below 0.40 means the same person. We chose 0.40 instead of the default 0.68 for stricter security in an exam context.

PERSON 2: One key design decision: we use DeepFace as primary and LBPH — Local Binary Pattern Histogram — as an automatic fallback. If TensorFlow is unavailable for any reason, the system seamlessly switches to LBPH so the exam is never blocked.

Person 3 — MQTT & QR Security (17:30 – 19:00)

PERSON 3: MQTT stands for Message Queuing Telemetry Transport. It's a publish-subscribe protocol designed for IoT devices. Think of it like a radio channel — the WROOM broadcasts on the exam/cam/command channel, and the CAM is tuned to that channel and acts on whatever it hears. They never talk directly to each other.

PERSON 3: For QR security, each code contains the student's UUCMS ID, room ID, and valid date range, plus a SHA256 cryptographic hash of all of that combined with a secret key stored only on the server. SHA256 is a one-way hash — you cannot reverse-engineer the original data from the hash, and you cannot forge a valid hash without the secret. So if a student photographs someone else's QR and tries to modify the roll number, the hash won't match and it's rejected immediately.

Rachana — State Machine & System Reliability (19:00 – 20:00)

RACHANA: The WROOM firmware is built as a finite state machine with 8 states. This is the correct architecture for embedded door controllers. Without it, you get race conditions — what happens if a buzzer alarm fires while an RFID scan is in progress? The state machine prevents impossible states by only allowing certain operations in each state.

RACHANA: We also built three layers of reliability. First, a non-blocking buzzer using millis() timing instead of delay() — so the keypad and RFID reader keep working even while the buzzer beeps. Second, a trespass confirmation counter requiring 3 consecutive sensor readings before triggering — eliminating false alarms. Third, a CAM ping-pong mechanism — the WROOM actively checks whether the camera is online before attempting face recognition, and waits up to 3 seconds for a response.

SECTION 5 — Q&A Preparation | 20:00 – 25:00

NOTE: Use these prepared answers. Whoever knows the topic best answers first. Others can add one sentence.

Q: Why not just use RFID alone? Why add face recognition?	
RACHANA	RFID alone can't prevent proxy attendance — a student can hand their card to a friend. Face recognition verifies the person is physically present. Together they form a genuine two-factor system.
PERSON 2	From a security standpoint, RFID is something you have, face is something you are. Two-factor authentication requires both categories.

Q: What happens if the internet goes down during the exam?	
PERSON 2	The entire system runs on a local WiFi hotspot with no internet dependency. Server.py, the MQTT broker, and SQLite database all run on the laptop. Internet is only used for SMS notifications — if that fails, the student PIN still shows on the OLED.

Q: What if a student is genuinely not recognized by the face scanner?	
RACHANA	There are three fallback levels. Fallback 1 is QR code from their hall ticket. Fallback 2 is emergency PIN given by the invigilator. The emergency PIN is generated fresh every exam day. No student can ever be permanently locked out.
PERSON 3	The fallback chain was a core design requirement — we didn't want the system to be a blocker. It only adds security on top of the existing process, never replaces the human judgment of the invigilator.

Q: How does the QR tamper detection work?	
PERSON 2	When we generate a QR, server.py creates a payload string — student ID, room, and exam dates — and computes its SHA256 hash using a secret key. This hash is embedded in the QR. On scanning, the same hash is recomputed from the scanned data and compared. If anyone modifies any field, the hash won't match.
PERSON 3	Additionally each QR can only be used once per exam day. A second scan returns 'already used today'. The same QR resets at midnight so the student can use it for the next exam day.

Q: What is the database used and why?	
PERSON 2	We use SQLite — a serverless, file-based relational database. It's appropriate for a single-hall deployment with up to a few hundred students. For multi-campus scaling, the backend architecture is portable to PostgreSQL with minimal changes — the SQL queries are standard and we use parameterized queries throughout to prevent SQL injection.

Q: How long does entry take? Is this faster than manual roll call?	
RACHANA	Primary flow — RFID plus face recognition — takes approximately 3 to 5 seconds per student. For a 60-student hall that's 5 minutes maximum versus 15 minutes for manual roll call. That's a 3x improvement.

Q: Why ESP32 and not Raspberry Pi?	
RACHANA	ESP32 is ideal for this door controller use case — it has built-in WiFi, real-time GPIO capabilities, costs around ₹300, and its dedicated hardware peripherals for SPI and I2C give reliable RFID and OLED communication. The Raspberry Pi runs a full Linux OS which introduces unpredictable latency for keypad scanning.
PERSON 2	The laptop handles the compute-intensive work — DeepFace, database, dashboard. The ESP32 handles the time-sensitive physical interaction. This division of responsibility gives us the best of both.

Q: Is this deployable in a real college?	
PERSON 2	Yes, with two additions we're actively working toward. First, PCB fabrication to replace the breadboard for a clean professional form factor. Second, replacing the laptop with a Raspberry Pi 4 as the server node to make it fully standalone. The software is already production-grade — all edge cases handled, fallback chain complete, and comprehensive audit logs.

Q: How do you handle the case where two students try to enter simultaneously?	
RACHANA	The state machine on the WROOM handles one authentication at a time. If a second student approaches during an active authentication, the trespass detection is paused — we only trigger trespass detection in state 0, the idle state. The second student would need to wait for the first to complete.
PERSON 3	For a real multi-lane deployment, each lane would have its own WROOM and ESP32-CAM, all connecting to the same server.py backend. The database is designed to handle concurrent entries from multiple rooms.

CLOSING STATEMENT | 24:00 – 25:00

NOTE: All three stand. Person 2 closes. Brief and confident.

PERSON 2: To summarize — SENTINEL is a complete multi-factor authentication system for exam halls that is faster, more secure, and more informative than any manual process. It stores photo proof of every entry, catches wrong rooms instantly, alerts on trespass, and gives the admin a live view of every hall.

PERSON 2: The system uses state-of-the-art ArcFace face recognition, cryptographically secured QR codes, and a robust fallback chain ensuring no student is ever locked out. It is built on production-grade software architecture and is ready to scale to real deployment with PCB fabrication.

PERSON 2: Thank you. We are happy to answer any questions.

→ CUE: All three stand confidently. Rachana holds hardware visible. Dashboard on screen.

IF SOMETHING FAILS — BACKUP PLAN

Reference

Hardware/CAM not connecting:

Skip to QR fallback demo — only needs laptop webcam, no CAM required. Say: 'We will demonstrate the QR fallback which uses the laptop webcam — this is actually how deployed exam systems handle it in practice.'

Server.py crashes:

Restart it: python server.py. While restarting, Person 2 walks through the code on screen explaining what each section does. Evaluators respect calm problem-solving.

Face recognition keeps failing:

Raise DEEPFACE_THRESHOLD to 0.55 in server.py and restart. Or switch to QR fallback demo — say: 'This demonstrates our fallback chain working exactly as designed.'

MQTT not connecting:

Run: net start mosquitto (as admin). Takes 5 seconds. Say: 'Just restarting the MQTT broker — this runs as a Windows service and occasionally needs a manual restart.'

Complete hardware failure:

Show previous successful demo screenshots/video. Walk through code on screen instead. Say: 'We will walk through the code directly — the system was fully working as recently as last night.' Evaluators respect honesty far more than panic.

You built something genuinely impressive. Present it confidently. Good luck! 🎉
